INCOMPLETENESS FOR STABLY COMPUTABLE THEORIES

YASHA SAVELYEV

ABSTRACT. Using the theory of Turing machines, we give a set theoretic reframing of Gödel's first and second incompleteness theorems, and its extension to Σ_2 definable theories (with further extension to Σ_n indicated). The usual Hilbert–Bernays provability conditions, the diagonal lemma, and even numerals are absent, replaced by a more direct diagonalization argument, from first principles, based in set theory. To this end, we partially categorify the theory Gödel encodings, which might be of independent interest. There are various upshots. We show that Gödel sentence, even in the Σ_2 (and likely Σ_n) case, is computably constructive. Moreover, our set theory reframed version of the second incompleteness theorem looks to be stronger (even in the base Σ_1 case) than the classical analogue. In an appendix, we formalize a version of the partly physical argument of Roger Penrose.

1. INTRODUCTION

For an introduction/motivation based around physical ideas the reader may see Appendix A. We begin by quickly introducing the notion of stable computability, in a specific context of formal theories.

Our setup will be mostly language agnostic. Let $\mathcal{L}$ be a first order language, in particular a formal language in a finite alphabet including the symbols of first order logic, with syntax of first order logic, such that elements of $\mathcal{L}$ are sentences (in the logical sense). Let $\mathcal{A}$ denote the first order language of arithmetic with non-logical symbols $\{0, +, \times, s, <\}$. (Or any chosen language of arithmetic sufficient to express Peano axioms.) We assume from now on that there is some fixed interpretation in $\mathcal{L}$ of the language $\mathcal{A}$, meaning a syntax and inference preserving embedding $\mathcal{A} \to \mathcal{L}$.

A theory F is a subset $F \subset \mathcal{L}$. F will be called deductively complete if it is closed under inference.

We will write $F \vdash Q$, to mean that given the interpretation of $\mathcal{A}$ as above, that F proves the axioms of Robinson arithmetic Q, similarly with $F \vdash PA$, for PA the Peano arithmetic. We will write $F_{\mathcal{A}}$ to mean the set of sentences of arithmetic proved by F under the given interpretation.

(1.1)   We may understand $F_{\mathcal{A}}$ as being a subset of $\mathcal{A}$.

Suppose we are given a map
$$M : \mathbb{N} \to \mathcal{L} \times \{\pm\},$$
for $\{\pm\}$ denoting a set with two elements $+, -$.

Definition 1.2.

- $\alpha \in \mathcal{A}$ **is M-stable** *if there is an m with $M(m) = (\alpha, +)$ s.t. there is no $n > m$ with $M(n) = (\alpha, -)$. Let $M^s \subset \mathcal{L}$ denote the set of M-stable α, called* **the stabilization of M**.

Remark 1.3. *For an informal motivation of how such an M may appear in practice consider the following. With $\mathbb{N}$ playing the role of time, M might be a device producing sentences of arithmetic that it believes to be true, at each moment $n \in \mathbb{N}$. But M is also allowed to correct itself in the following sense.*

- *$M(n) = (\alpha, +)$, only if at the moment n M decides that α is true.*

- *$M(m) = (\alpha, -)$, only if at the moment m, M no longer asserts that α is true, either because at this moment M is no longer able to decide α, or because it has decided it to be false.*

Definition 1.4. *A subset $S \subset \mathcal{L}$, is called* **stably computably enumerable** *or stably c.e., if there is a computable map (see Definition 2.2) $T : \mathbb{N} \to \mathcal{L} \times \{\pm\}$ so that $S = T^s$. We say that $T \in \mathcal{T}$* **stably computes** $M : \mathbb{N} \to \mathcal{L} \times \{\pm\}$, *if it computes some $N : \mathbb{N} \to \mathcal{L} \times \{\pm\}$, s.t. $M^s = N^s$.*

It is fairly immediate that a stably c.e. S is Σ_2 definable. The converse is also true, every Σ_2 definable set is stably c.e.. To prove this we may build on Example 3.3, to construct an oracle and then use the theorems of Post, (see [13]), relating the arithmetic hierarchy with the theory of Turing degrees. We omit the details as this will not be essentially used, and is a well understood idea.

Let $\mathcal{F}_0$ denote the set of Q-decidable formulas ϕ in arithmetic $\mathcal{A}$ with one free variable. We recall, see for instance [4], the following:

Definition 1.5. *Given a theory F, we say that it is* 1**-consistent**, *if for any formula $\phi \in \mathcal{F}_0$ the following holds:*
$$(F_{\mathcal{A}} \vdash \exists m\ \phi(m)) \implies (\exists m\ F_{\mathcal{A}} \nvdash \neg\phi(m)).$$
In other words, this says that $F_{\mathcal{A}}$ is 1-consistent, (see (1.1)). We say that it is 2**-consistent** *if the same holds for Π_1 formulas ϕ with one free variable, more specifically formulas $\phi = \forall n\ g(m,n)$, with g Q-decidable.*

The following are theorems of ZFC, with provability predicates being naturally interpreted. The first theorem in particular tells us that the Gödel sentence is "computable" even for Σ_2 theories.

Theorem 1.6. *Let $\mathcal{L}$ be as above. There is a total computable map $\mathcal{G} : \mathcal{T} \to \mathcal{L}$, where the domain $\mathcal{T}$ is the set of Turing machines $\mathbb{N} \to \mathbb{N}$, with $\mathcal{G}$ satisfying the following. Suppose T that stably computes $M : \mathbb{N} \to \mathcal{L} \times \{\pm\}$. Let $F = M^s$. Then we have:*

(1) *$F \nvdash \mathcal{G}(T)$ if F is 1-consistent.*

(2) *$F \nvdash \neg\mathcal{G}(T)$ if F is 2-consistent.*

(3)

(1.7) $(F \text{ is 1-consistent}) \implies \mathcal{G}(T),$

   is a theorem of PA. More formally stated, the sentence (1.7) is equivalent in ZFC to an arithmetic sentence provable by PA. In particular, $\mathcal{G}(T)$ is true in the standard model of arithmetic whenever F is 1-consistent.

Furthermore, the Turing machine computing $\mathcal{G}$, can itself be given constructively.

The above leads to set theory based versions of Gödel's second incompleteness theorem. Let $\mathcal{Z}$ denote the set of first order sentences in the language of set theory. In what follows by a *definable* theory $F \subset \mathbb{Z}$ we mean a set F which is definable in set theory.

Theorem 1.8. *Let F be a definable theory [1] in the language of set theory s.t. $F \vdash ZFC$. (As before interpreted in ZFC itself.) Then if F is strongly consistent, (see Definition 5.11) we have:*

(1.9) $(F \nvdash F_{\mathcal{A}} \text{ is 1-consistent}) \vee (F \nvdash F_{\mathcal{A}} \text{ is stably computably enumerable}).$

The following reframes the original second incompleteness theorem of Gödel:

Theorem 1.10. *Let F be a definable theory in the language of set theory s.t. $F \vdash ZFC$. Then if F is strongly consistent (see Definition 5.11):*

(1.11) $(F \nvdash F_{\mathcal{A}} \text{ is consistent}) \vee (F \nvdash\ F_{\mathcal{A}} \text{ is computably enumerable}).$

This is proved by the same argument.

---

[1] In principle we only need $F_{\mathcal{A}}$ to be definable.

1.1. **Generalizations to Σ_n.** There are natural candidates for how to generalize the theorem above. We may replace $M : \mathbb{N} \to \mathcal{A} \times \{\pm\}$ by $M : \mathbb{N}^n \to \mathcal{A} \times \{\pm\}$, using this we can define a notion of n-stable computability, specializing to stable computability for $n = 1$. The above theorems should generalize to this setting of n-stable computability. In terms of arithmetic complexity this should be exactly the class Σ_{n+1}. We leave this for future developments.

2. SOME PRELIMINARIES

2.1. **Abstractly encoded sets and abstract Turing machines.** The material of this section will be used in the main argument. Working with encoded sets/maps as opposed to concrete subsets of $\mathbb{N}$/functions will have some advantages as we can construct computable maps axiomatically. This approach is in essence the *standard* approach, but in the latter such encoding systems are usually implicit. We need to make it explicit, due to much greater complexity of the kind encodings we need to use. (We make explicit the axioms for the encodings, the latter themselves are still left implicit, as this is well understood.)

Definition 2.1. *We denote by $\mathcal{T}$ the set of all Turing machines $T : \mathbb{N} \to \mathbb{N}$. We write $*T(n)$ for the computation sequence of the Turing machine T with input n. As usual, for $T \in \mathcal{T}$, T also denotes the underlying partial function with $T(n) = m$ if $*T(n)$ halts with output m, and undefined otherwise.*

An **encoding** of a set A is at the moment just an injective set map $e : A \to \mathbb{N}$. But we will need to axiomatize this further. We extend the collection of encodings to a structure of a category.

In what follows, a map is a partial map, unless we specify that it is total. The category $\mathcal{S}$ will be a certain small "arrow category" whose objects are maps $e_A : A \to \mathbb{N}$, for e_A an embedding called **encoding map of** A, determined by a set A. More explicitly, the set of objects $\mathrm{obj}\,\mathcal{S}$ of $\mathcal{S}$ consists of some set of pairs (A, e_A) where A is a set, and $e_A : A \to \mathbb{N}$ an embedding, determined by A. We may denote $e_A(A)$ by A_e.

We now describe the morphisms of $\mathcal{S}$.

Definition 2.2. *For (N, e_N), (M, e_M) in $\mathrm{obj}\,\mathcal{S}$. We say that $T \in \mathcal{T}$ **computes** a map $f : N \to M$ if T fits into a commutative diagram:*

$$
\begin{array}{ccc}
N & \xrightarrow{\ f\ } & M \\
\downarrow{\scriptstyle e_N} & & \downarrow{\scriptstyle e_M} \\
\mathbb{N} & \xrightarrow{\ T\ } & \mathbb{N}.
\end{array}
$$

*We say that $f : N \to M$ is **computable** if there exists a $T \in \mathcal{T}$ which computes f.*

Notation 1. We may just write $A \in \mathcal{S}$ for an object, with e_A implicit.

We call such an $A \in \mathcal{S}$ an **abstractly encoded set**. Then we set $hom_{\mathcal{S}}(N, M)$ to be the set of computable maps as above. Clearly, the composition of computable maps is computable so that $\mathcal{S}$ is a category we call a **Turing category**.

In addition, we ask that $\mathcal{S}$ satisfies the following axioms.

(1) For $A \in \mathcal{S}$, the set A_e is computable (recursive). Here, as is standard, a set $S \subset \mathbb{N}$ is called *computable* if both S and its complement are computably enumerable, with S called *computably enumerable* if there is a computable partial function $\mathbb{N} \to \mathbb{N}$ with range S.

(2) If $A, B \in \mathcal{S}$ then $A \times B \in \mathcal{S}$ and the projection maps $pr^A : A \times B \to A$, $pr^B : A \times B \to B$ are computable. Similarly for pr^B.

(3) If $f : A \to B$ is computable, and $g : A \to C$ is computable then $A \to B \times C$, $a \mapsto (f(a), g(a))$ is computable. This combined with Axiom 2 implies that if $f : A \to B$, $g : C \to D$ is computable then the map $A \times B \to C \times D$, $(a, b) \mapsto (f(a), g(b))$ is computable.

(4) The set $\mathbb{N}$ has the identity encoding $e_{\mathbb{N}} : \mathbb{N} \to \mathbb{N}$.

(5) The set $\mathcal{T}$ is encoded. The partial map
$$U : \mathcal{T} \times \mathbb{N} \to \mathbb{N},$$
$U(T, \Sigma) := T(\Sigma)$ whenever $*T(\Sigma)$ halts and undefined otherwise, is computable. We can understand a Turing machine computing U as the "universal Turing machine".

(6) The next axiom gives a prescription for construction of Turing machines. Let $A, B, C \in \mathcal{S}$, and suppose that $f : A \times B \to C$ is computable. Let $f^a : B \to C$ be the map $f^a(b) = f(a, b)$. Then there is a computable map
$$s : A \to \mathcal{T}$$
so that for each a $s(a)$ computes f^a.

(7) If $(A, e_A) \in \mathcal{S}$ and $B \subset A$ s.t. $e_A(B)$ is computable, then B is encoded. We call this the **induced encoding**.

(8) The final axiom is for utility. If $A \in \mathcal{S}$ then $L(A) \in \mathcal{S}$, where
$$L(A) = \bigcup_{n \in \mathbb{N}} Maps(\{0, \ldots, n\}, A),$$
and $Maps(\{0, \ldots, n\}, A)$ denotes the set of total maps. We also have:

   (a) Let $A \in \mathcal{S}$ and let
   $$\text{length} : L(A) \to \mathbb{N},$$
   be the length function, s.t. for $l \in L(\mathcal{A})$, $l : \{0, \ldots n\} \to A$, $\text{length}(l) = n$. Then length is computable.

   (b) Define
   $$P : L(A) \times \mathbb{N} \to A,$$
   $$P(l, i) := \begin{cases} l(i), & \text{if } 0 \le i \le \text{length}(l) \\ \text{undefined}, & \text{for } i > \text{length}(l). \end{cases}$$
   Then P is computable.

   (c) For $A, B \in \mathcal{S}$ and $f : A \to L(B)$ a partial map, suppose that:

   - The partial map $A \times \mathbb{N} \to B$, $(a, n) \mapsto P(f(a), n)$ is computable.

   - The partial map $A \to \mathbb{N}$, $a \mapsto \text{length}(f(a))$ is computable.

   Then f is computable.

Lemma 2.3. *If $f : A \to B$ is computable then the map $L(f) : L(A) \to L(B)$,*
$$l \mapsto \begin{cases} i \mapsto f(l(i)), & \text{if } f(l(i)) \text{ is defined for all } 0 \le i \le \text{length}(l) \\ undefined, & otherwise, \end{cases}$$
is computable. Also, the map $LU : \mathcal{T} \times L(\mathcal{U}) \to L(\mathcal{U})$,
$$l \mapsto \begin{cases} i \mapsto U(T, (l(i))), & \text{if } U(T, (l(i))) \text{ is defined for all } 0 \le i \le \text{length}(l) \\ undefined, & otherwise \end{cases}$$
is computable.

Proof. This is just a straightforward application of the axioms and Axiom 8 in particular. We leave the details as an exercise. □

The above axioms suffice for our purposes, but there are a number of possible extensions (dealing with other set theoretic constructions like the set theoretic sum). The specific such category $\mathcal{S}$ that we need will be clear from context later on. We only need to encode finitely many basic types sets. (The rest are determined from the product, and list constructors, etc.) For example, aside from $\mathbb{N}, \mathcal{T}$, the category $\mathcal{S}$ should contain $\mathcal{A}, \{\pm\}$, with $\{\pm\}$ a set with two elements $+, -$. The main naturality properties for the encoding of $\mathcal{T}$ are already stated as Axioms 5, 6. We can of course take the standard type of encoding for $\mathcal{T}$. We also fix the standard Gödel encoding of $\mathcal{A}$. The only naturality property for $\mathcal{A}$ that is that certain natural maps of the type (4.8) are computable. This is satisfied for the standard encoding.

The fact that such Turing categories $\mathcal{S}$ exist is a folklore theorem of computer science starting with the foundational work of Gödel, Turing and others. For example, Axiom 6, in classical terms, just reformulates the following elementary fact, which follows by the "s-m-n theorem" Soare [13, Theorem 1.5.5]. Given a classical 2-input Turing machine

$$T : \mathbb{N} \times \mathbb{N} \to \mathbb{N},$$

there is a Turing machine $s_T : \mathbb{N} \to \mathbb{N}$ s.t. for each m $s_T(m)$ is the Turing-Gödel encoding natural, of a Turing machine computing the map $n \mapsto T(m, n)$.

In modern terms, the construction of $\mathcal{S}$ is essentially a part of a definition of a computer programming language (with algebraic data types, e.g. Haskell.)

3. STABLE COMPUTABILITY AND ARITHMETIC

In this section, general sets, often denoted as B, are intended to be encoded. And all maps are partial maps, unless specified otherwise.

Definition 3.1. *Given a map:*

$$M : \mathbb{N} \to B \times \{\pm\},$$

We say that $b \in B$ is M-stable if there is an m with $M(m) = (b, +)$ and there is no $n > m$ with $M(n) = (b, -)$.

Definition 3.2. *Given a map*

$$M : \mathbb{N} \to B \times \{\pm\},$$

we define

$$M^s \subset B$$

*to be the set of all the M-stable b. We call this the **stabilization of** M. When M is morphism in $\mathcal{S}$, we say that $S \subset B$ is **stably c.e.** if $S = M^s$. We say that $T \in \mathcal{T}$ **stably computes** $M : \mathbb{N} \to B \times \{\pm\}$, if it computes $N : \mathbb{N} \to B \times \{\pm\}$, s.t. $M^s = N^s$.*

In general M^s may not be computable even if M is computable. Explicit examples of this sort can be readily constructed as shown in the following.

Example 3.3. Let *Pol* denote the set of all Diophantine polynomials, abstractly encoded. We can construct a total computable map

$$A : \mathbb{N} \to Pol \times \{\pm\}$$

whose stabilization consists of all Diophantine (integer coefficients) polynomials with no integer roots. Similarly, we can construct a computable map D whose stabilization consists of pairs (T, n) for $T : \mathbb{N} \to \mathbb{N}$ a Turing machine and $n \in \mathbb{N}$ such that $*T(n)$ does not halt.

In the case of Diophantine polynomials, here is an (inefficient) example. Fixing a suitable encoding of $\mathbb{Z}$. Let

$$Z : \mathbb{N} \to Pol, \quad N : \mathbb{N} \to \mathbb{Z}$$

be total bijective computable maps. The encoding of $Pol, \mathbb{Z}$ should be suitably natural so that in particular the map

$$E : \mathbb{Z} \times Pol \to \mathbb{Z}, \quad (n, p) \mapsto p(n)$$

is computable. In what follows, for each $n \in \mathbb{N}$, $A_n \in L(Pol \times \{\pm\})$. $\cup$ will be here and elsewhere in the paper the natural list union operation. More specifically, if

$$l_1 : \{0, \ldots, n\} \to B, \quad l_2 : \{0, \ldots, m\} \to B$$

are two lists then $l_1 \cup l_2$ is defined by:

(3.4) $$l_1 \cup l_2(i) = \begin{cases} l_1(i), & \text{if } i \in \{0, \ldots, n\} \\ l_2(i - n - 1), & \text{if } i \in \{n + 1, \ldots, n + m + 1\} \end{cases}.$$

If $B \in \mathcal{S}$, it is easy to see by the axioms of $\mathcal{S}$ that

$$\cup : L(B) \times L(B) \to L(B), \quad (l, l') \mapsto l \cup l'$$

is computable.

For $n \in \mathbb{N}$ define A_n recursively by: $A_0 := \emptyset$,

$$A_{n+1} := A_n \cup \bigcup_{m=0}^{n} (Z(m), d^n(Z(m))),$$

where $d^n(p) = +$ if none of $\{N(0), \ldots, N(n)\}$ are roots of p, $d^n(p) = -$ otherwise.

Note that

$$(\forall n \in \mathbb{N}) \ A_{n+1}|_{\text{domain } A_n} = A_n, \text{ and } \text{length}(A_{n+1}) > \text{length}(A_n),$$

so we may define $A(n) := A_{n+1}(n)$. With this definition $A(\mathbb{N}) = \cup_{n \in \mathbb{N}} \text{image}(A_n)$.

Since E is computable, utilizing the axioms, and the recursive program above, it can be explicitly verified that A is computable. Moreover, by construction the stabilization A^s consists of all Diophantine polynomials that have no integer roots.

3.1. Decision maps.

By a ***decision map***, we mean a map of the form:

$$D : B \times \mathbb{N} \to \{\pm\}.$$

This kind of maps will play a role in our arithmetic incompleteness theorems, and we now develop some of their theory.

Definition 3.5. *Let $B \in \mathcal{S}$, define $\mathcal{D}_B$ to be the set of $T \in \mathcal{T}$ s.t. exists $T' : B \times \mathbb{N} \to \{\pm\}$, and a commutative diagram:*

$$\begin{array}{ccc} B \times \mathbb{N} & \xrightarrow{T'} & \{\pm\} \\ \downarrow{\scriptstyle e_{B \times \mathbb{N}}} & & \downarrow{\scriptstyle e_{\{\pm\}}} \\ \mathbb{N} & \xrightarrow{T} & \mathbb{N}. \end{array}$$

More concretely, this is the set of T s.t.:

$$(\forall n \in \text{image}_{B \times \mathbb{N}} \subset \mathbb{N}) \ T(n) \in \text{image} \, e_{B \times \{\pm\}} \text{ or } T(n) \text{ is undefined.}$$

As $e_{\{\pm\}}$ is injective, T' above is uniquely determined *if* it exists. From now on, for $T \in \mathcal{D}_B$, when we write T' it is meant to be of the form above.

First we will explain one construction of elements of $\mathcal{D}_B$. From Turing machines of the following form.

Definition 3.6. *Let $B \in \mathcal{S}$. Define $\mathcal{T}_B$ to be the set of $T \in \mathcal{T}$ s.t. exists $T' : \mathbb{N} \to B \times \{\pm\}$, and a commutative diagram:*

$$\begin{array}{ccc} \mathbb{N} & \xrightarrow{T'} & B \times \{\pm\} \\ \downarrow{\scriptstyle e_{\mathbb{N}}} & & \downarrow{\scriptstyle e_{B \times \{\pm\}}} \\ \mathbb{N} & \xrightarrow{T} & \mathbb{N}. \end{array}$$

From now on, given $T \in \mathcal{T}_B$, if we write T' then it is will be assumed to be of the form above. As before, it is uniquely determined when exists.

Lemma 3.7. *For $(A, e_A) \in \mathcal{S}$ define the map:*

(3.8)
$$e_A^{-1} : \mathbb{N} \to A,$$

defined by

$$e_A^{-1}(n) = \begin{cases} e_A^{-1}(n), & \text{if } n \in \text{image } e_A \\ \text{undefined}, & \text{otherwise.} \end{cases}$$

Then e_A^{-1} is computable.

Proof. Let $T \in \mathcal{T}$ compute the map defined by

$$n \mapsto \begin{cases} n, & \text{if } n \in \text{image } e_A \\ \text{undefined}, & \text{otherwise.} \end{cases}$$

As image e_A is decidable T does exist.

Then clearly we have a commutative diagram:

$$\begin{array}{ccc} \mathbb{N} & \xrightarrow{e_A^{-1}} & A \\ \downarrow{\scriptstyle id} & & \downarrow{\scriptstyle e_A} \\ \mathbb{N} & \xrightarrow{T} & \mathbb{N}. \end{array}$$

$\square$

Lemma 3.9. *Let $B \in \mathcal{S}$. There is a computable total map*

$$K_B : \mathcal{T} \to \mathcal{T},$$

with the properties:

(1) *For each T, $K_B(T) \in \mathcal{T}_B$ and is total if T is total.*

(2) *If $T \in \mathcal{T}_B$ then $K_B(T)$ and T compute the same maps $\mathbb{N} \to B \times \{\pm\}$.*

Proof. Let $G : \mathcal{T} \times \mathbb{N} \to B \times \{\pm\}$ be the composition of the sequence of maps

$$\mathcal{T} \times \mathbb{N} \xrightarrow{U} \mathbb{N} \xrightarrow{e_{B \times \{\pm\}}^{-1}} B \times \{\pm\}.$$

Hence, G is a composition of computable maps and so is computable. By Axiom 6 there is an induced computable map $K_B : \mathcal{T} \to \mathcal{T}$ so that $K_B(T)$ is the encoding of $G^T : \mathbb{N} \to B \times \{\pm\}$, $G^T(n) = G(T, n)$. By construction, if $T \in \mathcal{T}_B$ then $T' = (K_B(T))'$. So that we are done. $\square$

3.1.1. *Constructing decision Turing machines.* We will need a few preliminaries as we need to deal with the following issue. A given Turing machine $\mathbb{N} \to B \times \{\pm\}$, may be totalized but this will preserve stability conditions. This will require a work around.

The following is well known:

Lemma 3.10. *There is a computable map $Tot : \mathcal{T} \to \mathcal{T}$ s.t. $\forall T \in \mathcal{T}$:*

(1) $Tot(T)$ *is total for each T.*

(2) $\mathrm{image}(Tot(T)) = \mathrm{image}\, T.$

Let

$$\pi_{\mathbb{N}} : \mathbb{N} \times B \times \{\pm\} \to \mathbb{N}$$
$$\pi_{B \times \mathbb{N}} : \mathbb{N} \times B \times \{\pm\} \to B \times \{\pm\}$$

be the natural projections. We say that a subset $S \subset \mathbb{N} \times B \times \{\pm\}$ is *graphical*, if $\pi_{\mathbb{N}}^{-1}(n)$ is at most one element for each $n \in \mathbb{N}$.

On a graphical $S \subset \mathbb{N} \times B \times \{\pm\}$ there is a natural total order $s \leq s'$ if $\pi_{\mathbb{N}}(s) \leq \pi_{\mathbb{N}}(s')$. So a finite graphical $S \subset \mathbb{N} \times B \times \{\pm\}$ determines a list $l_S \in L(B \times \{\pm\})$ by

$$(3.11) \qquad\qquad\qquad l_S(i) = \pi_{B \times \{\pm\}}(s_i),$$

where s_i is the $i-1$ element of S with respect to the total order.

Definition 3.12. *Let $l \in L(B \times \{\pm\})$. Define $b \in B$ to be l-**stable** if there is an $m \leq \mathrm{length}(l)$ s.t. $l(m) = (b, +)$ and there is no $m < k \leq \mathrm{length}(l)$ s.t. $l(k) = (b, -)$.*

Given a map $f : \mathbb{N} \to B \times \{\pm\}$ let $\mathrm{gr}\, f : \mathbb{N} \to \mathbb{N} \times B \times \{\pm\}$ be the map $\mathrm{gr}\, f(n) = (n, f(n))$. Expanding on Lemma 3.9 there is a total computable map:

$$(3.13) \qquad\qquad\qquad Gr_B : \mathcal{T} \to \mathcal{T},$$

with the property: $Gr_B(T)$ computes the map $\mathrm{gr}(K_B(T)')$.

Set

$$(3.14) \qquad\qquad f^T := (Tot \circ Gr_B(T))' := e_{\mathbb{N} \times B \times \{\pm\}}^{-1} \circ Gr_B(T) \circ e_{\mathbb{N}}.$$

So that $f^T : \mathbb{N} \to \mathbb{N} \times B \times \{\pm\}$. Finally, define

$$G : B \times \mathcal{T} \times \mathbb{N} \to \{\pm\}$$

to be the map:

$$G(b, T, n) = \begin{cases} +, & b \text{ is } l_S\text{-stable, for } S = \mathrm{image}(f^T|_{\{0, \ldots n\}}). \\ -, & \text{otherwise.} \end{cases}$$

Lemma 3.15. *G is computable.*

Proof. This is clear, but we make this explicit. Let

$$(3.16) \qquad\qquad\qquad g : \mathbb{N} \to L(\mathbb{N})$$

be the map $g(n) = \{0, \ldots, n\}$, it is clearly computable directly by the Axiom 8. Let

$$L^{graph}(\mathbb{N} \times B \times \{\pm\}) \subset L(\mathbb{N} \times B \times \{\pm\})$$

consist of lists l s.t. $S = \mathrm{image}\, l$ is graphical. The latter subset has the induced encoding, see Axiom 7.

Then we can express G as the composition of the sequence of maps:

$$B \times \mathcal{T} \times \mathbb{N} \xrightarrow{id \times (Gr_B) \times g} B \times \mathcal{T} \times L(\mathbb{N}) \xrightarrow{id \times L(U)} B \times L(\mathbb{N})$$

$$\xrightarrow{id \times L(e_{\mathbb{N} \times B \times \{\pm\}}^{-1})} B \times L^{graph}(\mathbb{N} \times B \times \{\pm\}) \xrightarrow{id \times ord} B \times L(B \times \{\pm\}) \to \{\pm\},$$

where

(1) $ord : L^{graph}(\mathbb{N} \times B \times \{\pm\}) \to L(B \times \{\pm\})$ is the map $ord(l) = l_S$, for $S = \text{image } l$.

(2) The last map is:
$$(b,l) \mapsto \begin{cases} +, & \text{if } b \text{ is } l\text{-stable} \\ -, & \text{otherwise.} \end{cases}$$

The latter two maps are computable by explicit verification, utilizing the axioms. In particular all the maps in the composition are computable and so G is computable.

$\square$

Let

(3.17)
$$Dec_B : \mathcal{T} \to \mathcal{T},$$

be the computable total map corresponding G via Axiom 6, so that $Dec_B(T)$ is the Turing machine computing
$$G^T : B \times \mathbb{N} \to \{\pm\}, \quad G^T(b,n) = G(b,T,n).$$

The following is immediate from the construction:

Lemma 3.18. $Dec_B(T)$ has the property:
$$\forall T \in \mathcal{T} \; Dec_B(T) \in \mathcal{D}_B.$$

Furthermore, $Dec_B(T)$ is total.

Definition 3.19. For a map $D : B \times N \to \{\pm\}$, we say that $b \in B$ is D-**decided** if there is an m s.t. $D(b,m) = +$ and for all $n \geq m$ $D(b,n) \neq -$. Likewise, for $T \in \mathcal{D}_B$ we say that $b \in B$ is T-**decided** if it is T'-decided. Also for $T \in \mathcal{T}_B$ we say that b is T-**stable** if it is T'-stable in the sense of Definition 3.1.

Lemma 3.20. Suppose that $T \in \mathcal{T}_B$ then b is T-stable iff b is $Dec_B(T)$-decided.

Proof. Suppose that b is T-stable. In particular, there is an $m \in \mathbb{N}$ so that $T(m) = (b,+)$ and there is no $n > m$ so that $T(m) = (b,-)$. By construction, there exists an m' s.t. $f^T(m') = (m,b,+)$. It is then immediate that b is l_S-stable, for any $S_n = \text{image}(f^T|_{\{0,\ldots,n\}})$ s.t. $n \geq m'$.

Then by construction of G, $G(b,T,m') = +$ and there is no $n > m'$ s.t. $G(b,T,m') = -$. Thus b is G^T-decided and so $Dec_B(T)$-decided.

The converse is also clear. Suppose b is G^T decided. Let N be s.t.

(1) $G(b,T,N) = +$.

(2) There is no $n > N$ s.t. $G(b,T,n) = -$.

By 1 there is an $n_0 \in \{0,\ldots,N\}$ s.t. $f^T(n_0) = (n_b,b,+)$ and there is no $n \in \{0,\ldots,N\}$ with $pr_{\mathbb{N}} \circ f^T(n) > n_b$ s.t. $pr_{B \times \{\pm\}} \circ f^T(n) = (b,-)$.

Now, if b is not T-stable then there is a $n' > n_b$ s.t. $T(n') = (b,-)$. By the previous paragraph,
$$n' \notin \text{image } pr_{\mathbb{N}} \circ f^T|_{\{0,\ldots,N\}}.$$

So there is an $n > N$ so that $f^T(n) = (n', b, -)$. But then $G(b, T, n) = -$ which contradicts 2. $\qquad \square$

Example 3.21. By the Example 3.3 above there is a computable map
$$P = Dec_{Pol}(A) : Pol \times \mathbb{N} \to \{\pm\}$$
that stably soundly decides if a Diophantine polynomial has integer roots, meaning:
$$p \text{ is } P\text{-decided} \iff p \text{ has no integer roots.}$$
We may similarly, stably solve the halting problem, in this sense.

Definition 3.22. *Given a pair of maps*
$$M_0 : B \times \mathbb{N} \to \{\pm\}$$
$$M_1 : B \times \mathbb{N} \to \{\pm\},$$
we say that they are **stably equivalent** *if*
$$b \text{ is } M\text{-decided} \iff b \text{ is } M'\text{-decided.}$$
If $T \in \mathcal{D}_B$ then we say that T stable computes M iff T' is stably equivalent to M.

3.2. **Decision maps in formal systems.** Let $\mathcal{L}$ be as in the Introduction. Let $\mathcal{T}_\mathcal{L}$ be as in Definition 3.6 with respect to $B = \mathcal{L}$. The following is a version for stably c.e. theories of the classical fact, going back to Gödel, that for a theory with a c.e. set of axioms we may computably enumerate its theorems. Moreover, the procedure to obtain the corresponding Turing machine is computably constructive.

Notation 2. Note that each $T \in \mathcal{T}_\mathcal{L}$, determines the set
$$(T')^s \subset \mathcal{L},$$
called the stabilization of T', we hereby abbreviate the notation for this set as T^s.

Lemma 3.23. *There is a computable total map:*
$$C : \mathcal{T} \to \mathcal{T}$$
so that $\forall T \in \mathcal{T} : C(T) \in \mathcal{T}_\mathcal{L}$. If in addition $T \in \mathcal{T}_\mathcal{L}$ then $(C(T))^s$ is the deductive closure of T^s.

Proof. Let $L(\mathcal{L})$ be the list construction on $\mathcal{L}$ as previously. The following lemma is classical and its proof is omitted.

Lemma 3.24. *There is a total computable map:*
$$\Phi : L(\mathcal{L}) \times \mathbb{N} \to \mathcal{L}$$
with the following property. For each $l \in L(\mathcal{L})$, $\Phi(\{l\} \times \mathbb{N})$ is the set of all sentences provable by the theory $F_l = \text{image } l$.

Using the map *ord* from Lemma 3.15, define a map
$$\zeta : L(\mathcal{L}) \times L^{graph}(\mathbb{N} \times \mathcal{L} \times \{\pm\}) \to \{\pm\}$$
by
$$\zeta(l, l') = \begin{cases} +, & \text{if for each } 0 \leq i \leq \text{length}(l), \, l(i) \text{ is } ord(l')\text{-stable.} \\ -, & \text{otherwise.} \end{cases}$$
Utilizing the axioms of $\mathcal{S}$ we readily see that ζ is computable.

Now define H to be the composition of the sequence of maps:

$$\mathcal{T} \times L(\mathbb{N}) \xrightarrow{Gr_{\mathcal{L}} \times id} \mathcal{T} \times L(\mathbb{N}) \xrightarrow{LU} L(\mathbb{N}) \xrightarrow{L(e^{-1}_{\mathbb{N} \times \mathcal{L} \times \{\pm\}})} L^{graph}(\mathbb{N} \times \mathcal{L} \times \{\pm\}).$$

All the maps in the composition are computable directly by the axioms of $\mathcal{S}$ and so H is computable.

We may now construct our map C. In what follows $\cup$ will be the natural list union operation as previously in (3.4). Set

$$L_n(\mathbb{N}) := \{l \in L(\mathbb{N}) | \max l \leq n, \ \max l \text{ the maximum of } l \text{ as a map}\}.$$

Let

$$pr_{\mathcal{L}} : \mathbb{N} \times \mathcal{L} \times \{\pm\} \to \mathcal{L}$$

be the natural projection. For $n \in \mathbb{N}$, define $U_n^T \in L(\mathcal{L} \times \{\pm\})$ recursively by $U_0^T := \emptyset$,

$$U_{n+1}^T := U_n^T \cup \bigcup_{l \in L_{n+1}(\mathbb{N})} \bigcup_{0 \leq m \leq n+1} (\Phi(L_{pr_{\mathcal{L}}} \circ H(T, l), m), \zeta(L_{pr_{\mathcal{L}}} \circ H(T, l), H(T, \{0, \ldots, n+1\}))).$$

As in Example 3.3 we define

$$U^T : \mathbb{N} \to \mathcal{L} \times \{\pm\}, \quad U^T(n) := U_{n+1}^T(n).$$

And this induces a total map

$$U : \mathcal{T} \times \mathbb{N} \to \mathcal{L} \times \{\pm\},$$

$U(T, n) := U^T(n)$. U is computable by explicit verification, utilizing the axioms of $\mathcal{S}$, and the recursive program for $\{U_n^T\}$. Hence, by the Axiom 6 there is an induced by U computable total map:

$$C : \mathcal{T} \to \mathcal{T},$$

s.t. for each $T \in \mathcal{T}$ $C(T)$ computes U^T.

By construction, this has the needed properties, and we are done. $\square$

Notation 3. Let $M : \mathbb{N} \to \mathcal{L} \times \{\pm\}$ be a map. To simplify notation we use from now the shorthand: $M \vdash \alpha$, for $M_{\mathcal{A}}^s \vdash \alpha$, whenever $\alpha \in \mathcal{A}$, and whenever this may cause no confusion.

Definition 3.25. *Let $\mathcal{F}_0$, as in the introduction, denote the set of formulas ϕ of arithmetic with one free variable so that $\phi(n)$ is an Q-decidable sentence for each n. Let $M : \mathbb{N} \to \mathcal{L} \times \{\pm\}$ be a map. We say that M is* **speculative** *if the following holds. Let $\phi \in \mathcal{F}_0$, and set*

(3.26) $$\alpha_\phi = \forall m \ \phi(m),$$

then

$$(\forall m \ Q \vdash \phi(m)) \implies M \vdash \alpha_\phi.$$

Note that of course the left-hand side is not the same as $Q \vdash \alpha_\phi$.

Remark 3.27. *In a more broad context this condition is sometimes called the ω-rule for a theory.*

Note that we previously constructed an Example 3.3 of a Turing machine, with an analogue of this speculative property. Moreover, we have the following crucial result, which to paraphrase states that there is an operation *Spec* that converts a stably c.e. theory to a speculative stably c.e. theory, at a certain loss of consistency.

Theorem 3.28. *There is a computable total map $Spec : \mathcal{T} \to \mathcal{T}$, with the following properties:*

(1) image $Spec \subset \mathcal{T}_{\mathcal{A}}$.

(2) *Let $T \in \mathcal{T}_{\mathcal{A}}$. Set $T_{spec} = Spec(T)$ then T'_{spec} is speculative, moreover if T' is total then so is T'_{spec}.*

(3) *Using Notation 2, if $T \in \mathcal{T}_{\mathcal{A}}$ then $T^s_{spec} \supset T^s$*

(4) *If $T \in \mathcal{T}_{\mathcal{A}}$ and T^s is 1-consistent then T^s_{spec} is consistent.*

Proof. $\mathcal{F}_0, \mathcal{A}$ are assumed to be encoded so that the map

$$ev : \mathcal{F}_0 \times \mathbb{N} \to \mathcal{A}, \quad (\phi, m) \mapsto \phi(m)$$

is computable. We then need:

Lemma 3.29. *There is a total computable map $F : \mathbb{N} \to \mathcal{F}_0 \times \{\pm\}$ with the property:*

$$F^s = G := \{\phi \in \mathcal{F}_0 \,|\, \forall m \; Q \vdash \phi(m)\}.$$

Proof. The construction is analogous to the construction in the Example 3.3 above. Fix any total, bijective, Turing machine

$$Z : \mathbb{N} \to \mathcal{F}_0.$$

For a $\phi \in \mathcal{F}_0$ we will say that it is n-**decided** if

$$(\forall m \in \{0, \dots, n\}) \; Q \vdash \phi(m).$$

In what follows each F_n has the type of ordered finite list of elements of $\mathcal{F}_0 \times \{\pm\}$, and $\cup$ will be the natural list union operation, as previously. Define $\{F_n\}_{n \in \mathbb{N}}$ recursively by $F_0 := \emptyset$,

$$F_{n+1} := F_n \cup \bigcup_{\phi \in \{Z(0),\dots,Z(n)\}} (\phi, d^n(\phi)),$$

where $d^n(\phi) = +$ if ϕ is n-decided and $d^n(\phi) = -$ otherwise.

We set $F(n) := F_{n+1}(n)$. This is a total map

$$F : \mathbb{N} \to \mathcal{F}_0 \times \{\pm\},$$

having the property $F(\mathbb{N}) = \cup_n \mathrm{image}(F_n)$. F is computable by explicit verification, using the axioms of $\mathcal{S}$. □

Returning to the proof of the theorem. Let $K = K_{\mathcal{A}} : \mathcal{T} \to \mathcal{T}$ be as in Lemma 3.9. For $\phi \in \mathcal{F}_0$ let α_ϕ be as in (3.26). Define: $H : \mathcal{T} \times \mathbb{N} \to \mathcal{A} \times \{\pm\}$ by

$$H(T, n) := \begin{cases} (K_{\mathcal{A}}(T))'(k), & \text{if } n = 2k+1 \\ (\alpha_{pr_{\mathcal{F}_0} \circ F(k)}, pr_\pm \circ F(k)), & \text{if } n = 2k, \end{cases}$$

where $pr_{\mathcal{F}_0} : \mathcal{F}_0 \times \{\pm\} \to \mathcal{F}$, and $pr_\pm : \mathcal{F}_0 \times \{\pm\} \to \{\pm\}$ are the natural projections. H is computable directly by the axioms of $\mathcal{S}$. (Factor H as a composition of computable maps as previously.)

Let $Spec : \mathcal{T} \to \mathcal{T}$ be the computable map corresponding to H via Axiom 6. In particular, for each $T \in \mathcal{T}$, $Spec(T)$ computes the map

$$T'_{spec} := H^T : \mathbb{N} \to \mathcal{A} \times \{\pm\}, \quad H^T(n) = H(T, n),$$

which by construction is speculative. Now, $Spec(T)$ satisfies the Properties 1, 2, 3 immediately by construction. It only remains to check Property 4.

In what follows, let $T \in \mathcal{T}_{\mathcal{A}}$, and set $F_{spec} = (T'_{spec})^s$, and $F = (T')^s$.

Lemma 3.30. *F_{spec} consistent unless for some $\phi \in G$*

$$F \vdash \neg \forall m \; \phi(m).$$

Proof. Suppose that F_{spec} is inconsistent so that:

$$F \cup \{\alpha_{\phi_1}, \ldots, \alpha_{\phi_n}\} \vdash \alpha \wedge \neg \alpha$$

for some $\alpha \in \mathcal{A}$, and some $\phi_1, \ldots, \phi_n \in G$. Hence,

$$F \vdash \neg(\alpha_{\phi_1} \wedge \ldots \wedge \alpha_{\phi_n}).$$

But

$$\alpha_{\phi_1} \wedge \ldots \wedge \alpha_{\phi_n} \iff \forall m \, \phi(m),$$

where ϕ is the formula with one free variable: $\phi(m) := \phi_1(m) \wedge \ldots \wedge \phi_n(m)$. Clearly $\phi \in G$, since $\phi_i \in G$, $i = 1, \ldots, n$. Hence, the conclusion follows. $\square$

Suppose that F_{spec} inconsistent, then by the lemma above for some $\phi \in G$:

$$F \vdash \exists m \, \neg\phi(m).$$

By the hypothesis of Property 4, F is 1-consistent and so:

$$\exists m \, F \nvdash \phi(m).$$

But ϕ is in G, and $F \vdash Q$ so that $\forall m \, F \vdash \phi(m)$ and so

$$\exists m \, F \vdash \neg\phi(m) \wedge \phi(m).$$

So F is inconsistent, a contradiction, so F_{spec} is consistent. $\square$

4. The stable halting problem

Let $\mathcal{D}_{\mathcal{T}} \subset \mathcal{T}$ be as in Definition 3.5 with respect to $B = \mathcal{T}$.

Definition 4.1. *For $T \in \mathcal{D}_{\mathcal{T}}$, T is T-decided, is a special case of Definition 3.19. Or more specifically, it means that the element $T \in \mathcal{T}$ is T'-decided. We also say that T is not T-decided, when $\neg(T$ is T-decided$)$ holds.*

We call a map $D : \mathcal{T} \times \mathbb{N} \to \{\pm\}$ **a Turing decision map**. In what follows, denote by $s(T)$ the sentence:

$$(T \in \mathcal{D}_T) \wedge (T \text{ is not } T\text{-decided}).[2]$$

Definition 4.2. *We say a Turing decision map D is* **stably sound on $T \in \mathcal{T}$** *if*

$$(T \text{ is } D\text{-decided}) \implies s(T).$$

We say that D is **stably sound** *if it is stably sound on all T. We say that D* **stably decides** *T if:*

$$s(T) \implies T \text{ is } D\text{-decided}.$$

We say that D **stably soundly decides** *T if D is stably sound on T and D stably decides T. We say that D is* **stably sound and complete** *if D stably soundly decides T for all $T \in \mathcal{T}$.*

The informal interpretation of the above is that each such D is understood as an operation with the properties:

- For each T, n $D(T, n) = +$ if and only if D "decides" the sentence $s(T)$ is true, at the moment n.

- For each T, n $D(T, n) = -$ if and only if D cannot "decide" the sentence $s(T)$ at the moment n, or D "decides" that $s(T)$ is false.

—————————

[2]Written more formally this is the sentence $(T \in \mathcal{D}_T) \wedge ((T \in \mathcal{D}_T) \implies (T$ is not T-decided$))$, we will sometimes use this kind of contraction, and this will no longer be mentioned.

In what follows for $T \in \mathcal{T}$, and D as above, $\Theta_{D,T}$ is shorthand for the sentence:

$$T \text{ stably computes } D.$$

Lemma 4.3. *If D is stably sound on $T \in \mathcal{T}$ then*

$$\neg\Theta_{D,T} \vee \neg(T \text{ is } D\text{-decided}).$$

Proof. If T is D-decided then since D is stably sound on T, $T \in \mathcal{D}_{\mathcal{T}}$ and T is not T-decided. So if in addition $\Theta_{D,T}$ then T is not D-decided a contradiction. $\square$

The following is the "stable" analogue of Turing's halting theorem.

Theorem 4.4. *There is no (stably) computable Turing decision map D that is stably sound and complete.*

Proof. Let D be stably sound and complete. Then by the above lemma we obtain:

(4.5) $$\forall T \in \mathcal{T} : \Theta_{D,T} \vdash \neg(T \text{ is } D\text{-decided}).$$

But it is immediate:

(4.6) $$\forall T \in \mathcal{T} \; (\Theta_{D,T} \implies (\neg(T \text{ is } D\text{-decided})) \implies \neg(T \text{ is } T\text{-decided})) \, .$$

So combining (4.5), (4.6) above we obtain

$$\forall T \in \mathcal{T} \; (\Theta_{D,T} \implies \neg(T \text{ is } T\text{-decided})).$$

But D is complete so $(T \in \mathcal{D}_{\mathcal{T}}) \wedge \neg(T \text{ is } T\text{-decided}) \implies T$ is D-decided and so:

$$\forall T \in \mathcal{T} \; (\Theta_{D,T} \implies (T \text{ is } D\text{-decided})).$$

Combining with (4.5) we get

$$\forall T \in \mathcal{T} \; \neg\Theta_{D,T},$$

which is what we wanted to prove. $\square$

Theorem 4.7. *Suppose $F \subset \mathcal{A}$ is stably c.e. and sound theory, then there is a constructible (given a Turing machine stably computing F) true in the standard model of arithmetic sentence $\alpha(F)$, which F does not prove.*

The fact that such an $\alpha(F)$ exists, can be immediately deduced from Tarski undecidability of truth, as the set F must be definable in first order arithmetic by the condition that F is stably c.e. However, our sentence is constructible and elementary. Moreover, the basic form of this sentence will be used in the next section. The above theorem is partly based on meta logic. This is in sharp contrast to the syntactic incompleteness theorems in the following section which are actual theorems of ZFC.

Proof of Theorem 4.7. Suppose that F is stably c.e. and is sound. Let $M : \mathbb{N} \to \mathcal{A} \times \{\pm\}$ be a total computable map s.t. $F = M^s(N)$. Let $C(M_e)$ be as in Lemma 3.23, where M_e computes M. If we understand arithmetic as being embedded in set theory ZFC in the standard way, then for each $T \in \mathcal{T}$ the sentence $s(T)$ is logically equivalent in ZFC to a first order sentence in arithmetic, that we also call $s(T)$, slightly abusing notation. The corresponding translation map

(4.8) $$s : \mathcal{T} \to \mathcal{A}, T \mapsto s(T)$$

is computable. Indeed, this kind of translation already appears in the original work of Turing [1].

Define a Turing decision map D by

$$D(T, n) := (Dec_{\mathcal{A}}(C(M_e)))'(s(T), n)$$

for $Dec_{\mathcal{A}}$ as in (3.17) defined with respect to $B = \mathcal{A}$, and where C is as in Section 3. Then by construction, and by Axiom 3 in particular, D is computable by some Turing machine D_e, we make this more constructively explicit in the following Section 5.

Now D is stably sound by Lemma 3.20 and the assumption that F is sound. So by Lemma 4.3:

$$\neg(D_e \text{ is } D\text{-decided}).$$

In particular, $s(D_e)$ is not $Dec_{\mathcal{A}}(C(M_e))$-decided, and so $s(D_e)$ is not $C(M_e)$-stable (Lemma 3.20), i.e. $M \nvdash s(D_e)$.

On the other hand,

$$\neg(D_e \text{ is } D\text{-decided}) \models \neg(D_e \text{ is } D_e\text{-decided}),$$

by definition. And so since $D_e \in \mathcal{D}_{\mathcal{T}}$ by construction, $s(D_e)$ is satisfied. Set $\alpha(M) := s(D_e)$ and we are done. $\qquad\square$

5. Syntactic incompleteness for stably computable theories

Let $s : \mathcal{T} \to \mathcal{A}$, $T \mapsto s(T)$ be as in the previous section. Define

$$H : \mathcal{T} \times \mathcal{T} \times \mathbb{N} \to \{\pm\},$$

by $H(K, T, n) := (Dec_{\mathcal{A}}(C(Spec(K))))'(s(T), n)$. We can express H as the composition of the sequence of maps:

$$(5.1) \qquad \mathcal{T} \times \mathcal{T} \times \mathbb{N} \xrightarrow{(Dec_{\mathcal{A}} \circ C \circ Spec) \times s \times id} \mathcal{T} \times \mathcal{A} \times \mathbb{N} \xrightarrow{id \times e_{\mathcal{A} \times \mathbb{N}}} \mathcal{T} \times \mathbb{N} \xrightarrow{U} \mathbb{N} \xrightarrow{e_{\{\pm\}}^{-1}} \{\pm\},$$

where the last map is:

$$\Sigma \mapsto \begin{cases} \text{undefined}, & \text{if } \Sigma \notin \{\pm\}_e \\ e_{\{\pm\}}^{-1}(\Sigma), & \text{otherwise.} \end{cases}$$

Thus, H is a composition of maps that are computable by the axioms of $\mathcal{S}$ and so H is computable. Hence, by Axiom 6 there is an associated total computable map:

$$(5.2) \qquad\qquad\qquad\qquad Tur : \mathcal{T} \to \mathcal{T},$$

s.t. for each $K \in \mathcal{T}$, $Tur(K)$ computes the map

$$D^K : \mathcal{T} \times \mathbb{N} \to \{\pm\}, \ D^K(T, n) = H(K, T, n).$$

In what follows, $T \in \mathcal{T}_{\mathcal{A}}$, and we rename T' as M so $M : \mathbb{N} \to \mathcal{A} \times \{\pm\}$. As usual, notation of the form $M \vdash \alpha$ means $M^s \vdash \alpha$.

Proposition 5.3. *For (M, T) as above:*

$$M^s \text{ is 1-consistent} \implies M \nvdash s(Tur(T)).$$

$$M^s \text{ is 2-consistent} \implies M \nvdash \neg s(Tur(T)).$$

Moreover, the sentence:

$$M^s \text{ is 1-consistent} \implies s(Tur(T))$$

is a theorem of PA under standard interpretation of all terms, (this will be further formalized in the course of the proof).

Proof. This proposition is meant to just be a theorem of set theory ZFC, however we of course avoid complete set theoretic formalization, as is common. Arithmetic is interpreted in set theory the standard way, using the standard set $\mathbb{N}$ of natural numbers. So for example, for $M : \mathbb{N} \to \mathcal{A} \times \{\pm\}$ a sentence of the form $M \vdash \alpha$ is a priori interpreted as a sentence of ZFC, however if M is a Turing machine this also can be interpreted as a sentence of PA, once Gödel encodings (the category $\mathcal{S}$) are invoked.

Set $N := (C \circ Spec(T))'$, in particular this is a speculative map $\mathbb{N} \to \mathcal{A} \times \{\pm\}$. Suppose that $M \vdash s(Tur(T))$. In particular, $s(Tur(T))$ is N-stable, and so by Lemma 3.20 $s(Tur(T))$ is $Dec_{\mathcal{A}}(C(Spec(T)))$-decided, and so $Tur(T)$ is D^T-decided by definition. More explicitly, since D^T is total by construction, we deduce the sentence $\eta(T)$:

$$\exists m (\forall n \geq m) \, D(Tur(T), n) = +.$$

In other words:

$$(5.4) \qquad\qquad\qquad (M \vdash s) \implies \eta(T)$$

is a theorem of ZFC.

If we translate $\eta(T)$ to an arithmetic sentence with the same name, then it can be chosen to have the form:

$$\exists m \forall n \, \gamma(m, n),$$

where $\gamma(m, n)$ is Q-decidable. The sentence $s(Tur(T))$ is assumed to be of the form $\beta(T) \wedge \neg \eta(T)$, where $\beta(T)$ is the arithmetic sentence equivalent in ZFC to $Tur(T) \in \mathcal{D}_{\mathcal{T}}$. Clearly, the translation maps $\mathcal{T} \to \mathcal{A}$, $T \mapsto \beta(T)$, $T \mapsto \eta(T)$ can be taken to be total and computable. Moreover, applying Lemma 3.18 (interpreted as a Theorem of PA): we get

$$(5.5) \qquad\qquad\qquad PA \vdash \forall T \in \mathcal{T} \, \beta(T).$$

And so

$$(5.6) \qquad\qquad\qquad PA \vdash (\eta(T) \implies \neg s(Tur(T)).$$

Moreover, ZFC proves:

$$\begin{aligned}
\eta(T) &\implies \exists m \forall n \, Q \vdash \gamma(m, n), \quad \text{trivially} \\
&\implies \exists m : N \vdash \forall n \, \gamma(m, n), \quad \text{since } N \text{ is speculative} \\
&\implies N \vdash \eta(T), \\
&\implies N \vdash \neg s(Tur(T)), \quad \text{by (5.6) and since } N^s \supset PA.
\end{aligned}$$

And so combining with (5.4), (5.6) ZFC proves:

$$(M \vdash s) \implies (N \vdash s) \wedge (N \vdash \neg s).$$

Since by Theorem 3.28

$$M^s \text{ is 1-consistent} \implies N^s \text{ is consistent,}$$

it follows:

$$(5.7) \qquad ZFC \vdash (M^s \text{ is 1-consistent} \implies M \nvdash s(Tur(T)) \quad (\text{moreover } N \nvdash s(Tur(T)))).$$

Now suppose

$$(M^s \text{ is 2-consistent}) \wedge (M \vdash \neg s(Tur(T))).$$

Since we have (5.5), and since $M \vdash PA$ it follows that $M \vdash \eta(T)$.

Set

$$\phi(m) = \forall n \, \gamma(m, n).$$

Now,

$$\begin{aligned}
M \vdash \eta(T) &\iff M \vdash \exists m \, \phi(m) \\
&\implies \exists m \, M \nvdash \neg \phi(m), \quad \text{by 2-consistency.} \\
&\implies \exists m \forall n \, Q \vdash \gamma(m, n), \quad \text{as } M^s \supset Q \text{ and } \gamma(m, n) \text{ is } Q\text{-decidable.}
\end{aligned}$$

In other words, ZFC proves:

$$(M^s \text{ is 2-consistent} \wedge (M \vdash \neg s)) \implies \eta(T).$$

And ZFC proves:

$$\eta(T) \implies N \vdash s(Tur(T)),$$

by definitions. So ZFC proves:

$$(M^s \text{ is 2-consistent} \wedge (M \vdash \neg s(Tur(T)))) \implies N \vdash s(Tur(T))$$
$$\implies N^s \text{ is inconsistent}$$
$$\implies M^s \text{ is not 1-consistent, by Theorem 3.28}$$
$$\implies M^s \text{ is not 2-consistent.}$$

And so ZFC proves:

$$M^s \text{ is 2-consistent} \implies M \nvdash \neg s(Tur(T)).$$

Now for the last part of the proposition. We essentially just further formalize (5.7) and its consequences in PA. In what follows by equivalence of sentences we mean equivalence in ZFC. The correspondence of sentences under equivalence is the standard kind of correspondence assigning predicates involving Turing machines predicates in PA. The basic form of such correspondences is already constructed by Turing [1], so that we will not elaborate. In particular, the correspondences are computable, which just means that the corresponding maps $\mathcal{T} \to \mathcal{A}$ are computable.

Definition 5.8. *We say that $T \in \mathcal{T}$ is **stably 1-consistent** if $T \in \mathcal{T}_\mathcal{A}$ and T^s is 1-consistent, (Notation 2). The sentence "T^s is 1-consistent", can specifically be taken to be the arithmetic sentence $Con_{\sigma,1}$ for σ the natural Σ_2 definition of T^s and $Con_{\sigma,1}$ the consistency sentence as in [7, Section 5].*

Then the sentence:

$$T \text{ is stably 1-consistent}$$

is equivalent to an arithmetic sentence we denote:

$$1 - con^s(T).$$

The sentence $Spec(T) \nvdash s(Tur(T))$ is equivalent to an arithmetic sentence we call:

$$\omega(T).$$

By the proof of the first part of the proposition, that is by (5.7),

$$(5.9) \qquad ZFC \vdash \forall T \in \mathcal{T} \ (1 - con^s(T) \implies \omega(T)).$$

But we also have:

$$(5.10) \qquad PA \vdash \forall T \in \mathcal{T} \ (1 - con^s(T) \implies \omega(T)),$$

since the first part of the proposition can be formalized in PA, in fact the only interesting theorems we used are Lemma 3.20, and Theorem 3.28 which are obviously theorems of PA.

Now, by Lemma 3.20 and the construction of H:

$$PA \vdash \forall T \in \mathcal{T} \ \omega(T) \iff \neg\eta(T).$$

So:

$$PA \vdash \forall T \in \mathcal{T} \ (\beta(T) \wedge \omega(T) \iff s(Tur(T))),$$

Combining with (5.5) and with (5.10) we get:

$$PA \vdash \forall T \in \mathcal{T} \ (1 - con^s(T) \implies s(Tur(T))).$$

So for (M, T) as in the statement, if we formally interpret the sentence "M^s is 1-consistent" as the arithmetic sentence $1 - con^s(T)$, then this formalizes and proves the last part of the proposition. $\qquad \square$

Proof of Theorem [1.6]. The computable map $\mathcal{G}$ is defined to be $T \mapsto s(Tur(T))$. Then the theorem follow by the proposition above, applied to the pair $((K_{\mathcal{A}}(T))', K_{\mathcal{A}}(T))$. $\square$

Definition 5.11. *Given a theory F in the language of set theory, we say that it is* **strongly consistent** *if for any formula ϕ with one free variable, and any term S (i.e. a 'set') the following holds:*

$$(F \vdash \exists x \in S \ \phi(x)) \implies \exists x \in S \ F \nvdash \neg\phi(x).$$

Remark 5.12. *There is possibly a more standardized name for this, but I am not aware of it. This appears to be stronger then ω-consistency of Gödel, since the sentences $\phi(x)$ are not required to be arithmetic. Clearly, any sound theory F is strongly consistent.*

Proof of Theorem [1.8]. Let $F, F_{\mathcal{A}}$ be as in the hypothesis. By (5.7), and by (5.5)

$$(5.13) \qquad\qquad ZFC \vdash \forall T \in \mathcal{T}_{\mathcal{A}} \ ((T')^s \text{ is 1-consistent }) \implies s(Tur(T)).$$

Lemma 5.14. *ZFC proves:*

$$\forall T \in \mathcal{T} \ (F \nvdash T \text{ stably computes } F_{\mathcal{A}}.)$$

Proof. Suppose otherwise that

$$\exists T \ (F \vdash T \text{ stably computes } F_{\mathcal{A}}.)$$

Now, since $F \vdash ZFC$ by assumption, by (5.13) $F \vdash s(Tur(T))$. More specifically,

$$ZFC \vdash (F_{\mathcal{A}} \vdash s(Tur(T_0))).$$

But also

$$ZFC \vdash ((F_{\mathcal{A}} \vdash s(Tur(T_0))) \implies \neg(F_{\mathcal{A}} \text{ is 1-consistent}) \vee \neg(T_0 \text{ stably computes } F_{\mathcal{A}})).$$

Since $F \vdash ZFC$, we conclude that

$$F \vdash (\neg(F_{\mathcal{A}} \text{ is 1-consistent}) \vee \neg(T \text{ stably computes } F_{\mathcal{A}})).$$

So we get a contradiction, since F is consistent and by the assumption ($F \vdash F_{\mathcal{A}}$ is 1-consistent). $\square$

Since F is strongly consistent (using the contrapositive of the condition 5.11) it follows that:

$$F \nvdash (\exists T \in \mathcal{T} \ T \text{ stably computes } F_{\mathcal{A}}).$$

$\square$

Appendix A. Stable computability and physics - Gödel's disjunction and Penrose

We now give some partly physical motivation for the theory above, and in particular for the notion of stable computability. As this work is aimed at mathematicians, we aim to be very brief. But developing this appendix would be very interesting in an appropriate venue.

We may say that a physical process is *absolutely not Turing computable*, if it is not Turing computable in any "sufficiently physically accurate" mathematical model. For example, it is well known (see for instance [**?**]) that solutions of fluid flow and N-body problems are generally non Turing computable (over $\mathbb{Z}$, and probably over $\mathbb{R}$ cf. [3]) as modeled in mathematics of classical mechanics. But in a more physically accurate and fundamental model both of the processes above may become computable.

The question posed by Turing [2], but also by Gödel [6, 310] and more recently and much more expansively by Penrose [10], [11], [12] is:

Question 1. Are there absolutely not Turing computable physical processes? And moreover, are brain processes absolutely not Turing computable?

A.0.1. *Gödel's disjunction.* Gödel argued for a 'yes' answer to Question 1, see [6, pg. 310], relating the question to existence of absolutely unsolvable Diophantine problems, see also Feferman [5], and Koellner [8], [9] for a discussion.

We now discuss the question from the perspective of our main results. First by an idealized mathematician, we mean here a theory $\mathcal{H}$ in the language of set theory ZFC, s.t. $\mathcal{H} = H^s$ of some $H : \mathbb{N} \to \mathcal{Z} \times \{\pm\}$, with $\mathcal{Z}$ denoting the set of first order sentences of ZFC, or a superset thereof. See also Remark 1.3, H is meant to be the actual time stamped output of a mathematician, idealized so that their brain does not deteriorate in time.

The need to work with stabilizations is clear, as mathematicians are not consistent, however it seems that mathematical knowledge does stabilize on truth. Here we are using 'stabilize' in the more common language sense, but in this setting this is equivalent to the mathematical stabilization H^s. Hence soundness and in particular strong consistency (Definition 5.11) of the stabilization $\mathcal{H}$ is not an unreasonable hypothesis for our mathematician. For one discussion of the problem of idealization see Feferman [5]. We cannot do much justice to such considerations here.

Without delving deeply into interpretations, we suppose the following axioms for $\mathcal{H}$.

(1) $\mathcal{H}$ is definable in set theory. (This is natural, H is determined by some physical processes, and we expect that they can be formalized in set theory - colloquially they have mathematical models, which then determine a definition of $\mathcal{H}$.)

(2) $\mathcal{H} \vdash ZFC$.

(3) The "Penrose property": $\mathcal{H} \vdash \mathcal{H}_{\mathcal{A}}$ is 1-consistent, where $\mathcal{H}_{\mathcal{A}}$ is as in Theorem 1.8. (This might be informally interpreted as that our idealized mathematician knows the set theoretic definition of $\mathcal{H}$, and asserts that it is suitably consistent.)

The possibility that our mathematician indeed knows the definition of $\mathcal{H}$ is perhaps not unlikely, especially if Question 1 has a negative answer. Just map the brain, its synapses, etc.; then assuming one knows the working of all underlying physical processes, use this to reconstruct the set theoretic definition of $\mathcal{H}$. This would be a fantastically difficult thing to do, but not a priori impossible. Given this, there is no reason to reject the above axioms.

Applying Theorem 1.8 we then get the following pseudo-theorem. (It is not a 'theorem' since of course $\mathcal{H}$ is not at the moment properly defined.)

Pseudo-theorem A.1. *One of the following holds:*

(1) $\mathcal{H}$ *is not strongly consistent.*

(2) $\mathcal{H}$ *does not prove that* $\mathcal{H}_{\mathcal{A}}$ *is stably c.e. (We must interpret this as that our idealized mathematician represented by* $\mathcal{H}$ *is unable to disprove existence of absolutely non Turing computable physical processes.)*
